

Understand how your equipment is running

Pump readings, transfer records and repair details often live in different places. Kinetic connects the useful information so your team can explain normal operation, investigate changes and see what happened after service.

A connected system at the site

We review your equipment and existing controls, connect the agreed readings and add sensing where the job needs it. An onsite gateway collects and organizes the information. Local displays and remote software put equipment history within reach of the people who use it.

Compare operation with context

Review similar operating periods, explain interruptions and prepare reports from a consistent history. At a terminal, that may mean comparing transfers with similar products and routes. At a well group, it may mean reviewing equipment state alongside handling conditions and recent work.

Investigate a developing change

Configured monitoring analyzes available signals for conditions that deserve attention. The AI technician assistant helps explain findings and relevant approved checks. Technicians arrive with the operating context and previous work, then record what they found and changed.

Keep the operating result with the service record

Compare relevant operation after the visit. The next person can see both the reported work and whether the original condition has returned. That history supports maintenance decisions and a clearer discussion with service providers.

Begin with one useful question

Choose an equipment group, a routine report or a recent event. We will review the available information, the people who need it and the site connection, then define a practical first phase. Equipment, installation, subscription and support are set out in the proposal.
